

A NEW CONCEPT IN HANDLING MEGA-SHIPS

Frans Koch, CEO,
Koch Consultancy Group, Goes, Netherlands

KOCH Consultancy Group
Engineers Architects

Bigger ships mean more moves per call, which in turn means a logical requirement for additional berth capacity, or so conventional wisdom would state. This article contends that upgrading berth capacity alone in order to tackle mega-ships will lead to congestion throughout yard facilities. I believe that additional capacity can be achieved whilst avoiding the spectre of congestion by improving the efficiency of each quay crane at a berth and by increasing the number of quay cranes on one ship.

THE NGICT CONCEPT

Because the new generation integrated container terminal (NGICT) concept is so expansive and there's limited space with which to explore the many facets and nuances of the concept in this article, this piece touches only the main characteristics of this new concept and focuses on the stack area in most detail. This is because increasing the speed of stack operations is a direct challenge for every terminal in the world.

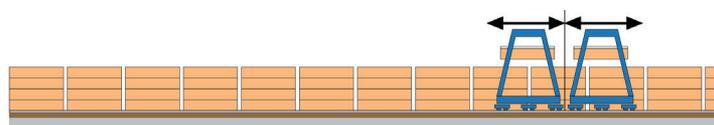

The main characteristics of the NGICT concept are as follows:

- Narrow ship-to-shore (STS) crane modules on high positioned rails which are able to work in adjacent bays of a ship
- A fixed support-structure in the STS area with waterside columns around 30m behind a quay wall
- The STS area and the stack area are fully integrated. This reduces the travel distance between these two areas for each container
- The STS area crane modules put containers on top of a two-directional AGV which operates parallel to a quay until the designated stack lane has been reached. At this point, the two-directional AGV drives over a short distance in a perpendicular direction until a container is underneath stack overhead bridge cranes
- The special stack overhead bridge cranes can pass each other in one and the same stack lane and drive perpendicular to the quay from an STS area to a truck and train area. This way no other horizontal transport devices at ground level are needed

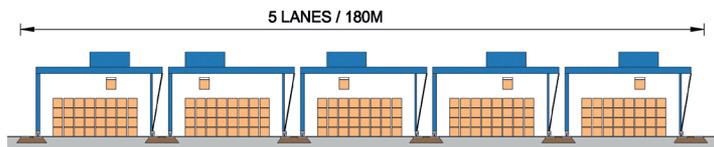

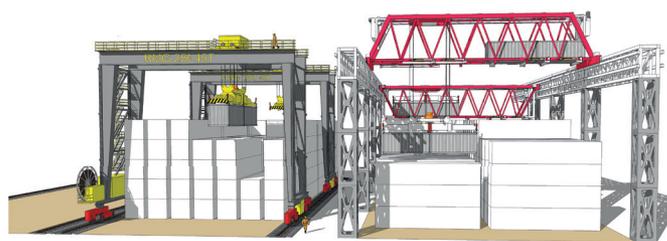

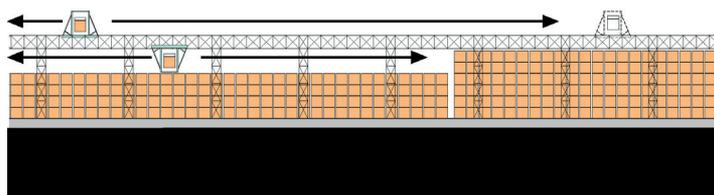

STACK OPERATIONS: OVERHEAD BRIDGE CRANES

As automation becomes the key driver for efficiency in container terminal operations, it is important to remember that innovation began initially with RMG's and, at a later stage, RTGs. Although OHBCs (overhead bridge cranes) at that time were equal in multi criteria comparisons to RMGs, they did not become the standard and dropped out of sight. Only a few terminals in the world have chosen an OHBC configuration since automation, and after this, the OHBC case has not been easy to argue.

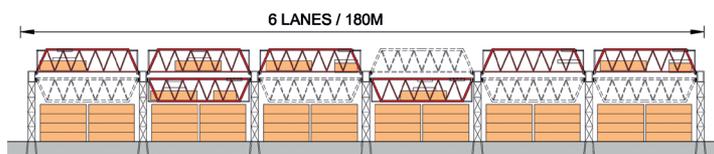

Since that time, there has been no development in the OHBC-system at all, and in the meantime, the RMG and RTG cranes have reached a very high level of automated technology. Nowadays, at many automated terminals, stack operations are carried out with RMGs that are generally aligned perpendicular to the quay. Each stack lane has two RMGs running on the same set of rails on ground level. The length of stack lanes vary between 250 and 400m, and the stacking height is 1-over-4, or 1-over-5.

STACK LENGTH 200 / 500M

RMG'S STACK DENSITY 1500 TEU/HECTARE
STACK 1 OVER 4 PERPENDICULAR TO THE QUAY

OHC'S STACK DENSITY 1900 TEU/HECTARE
STACK 1 OVER 4 PARALLEL TO THE QUAY

OHBC VS RMG

Despite this optimal state-of-the-art process, we cannot close our eyes to the logistical disadvantages which occur in the case of variations in workload. In all studies, the RMG and the OHBC have had the same problem; they cannot pass each other in the same stack lane. Since we have solved that problem by inventing an 'upper-OHBC' and an 'under-OHBC', which are able to pass each other in one and the same stack lane, it thus becomes possible to double the stack performance and to follow production changes between water side and land side demands.

For example, in one stack lane, two OHBCs are working at the water side and one OHBC at the land side. In long stack lanes, more than three or four OHBCs could be installed to achieve higher performance and a better distribution of the workload. As said before, the special OHBCs are made in two models, one with a so-called 'under frame work' and one with an 'upper frame work'.

The rails for the 'upper OHBC' and for the 'under OHBC' are connected to one common girder and supported by common columns (see Figure 2). The height of the columns can be adjusted to the number of stacking layers of containers. By the trussed-frame, the weight of an OHBC is much lighter than the weight of a usual overhead crane and therefore much faster and energy saving. Above that, a trussed-frame affords the space to carry a container completely inside a crane.

Each OHBC can be equipped with an extra support system across the bottom members that makes it possible (by using one spreader) to carry two 40ft containers at the same time. Another advantage of the system is that it offers maximum redundancy because the 'upper OHBC' is able to carry the 'under OHBC' in case of a breakdown, and the other way round. This level of flexibility would result in a higher performance for the whole stacking process.

A standard OHBC costs less than 50% of a standard RMG, while its weight is approximately 15% to that of an RMG. Furthermore, the travelling speed is higher, the energy consumption is lower, and last but not least, the stack density is much higher.

STRUCTURE

The support structure for an OHBC, consisting of standard steel columns and trussed girders including piled foundations, is built uniquely due to an inventive and integrated modular design which is very economical. The stack density is almost 30% higher than in the case of RMG's.

COST BENEFIT

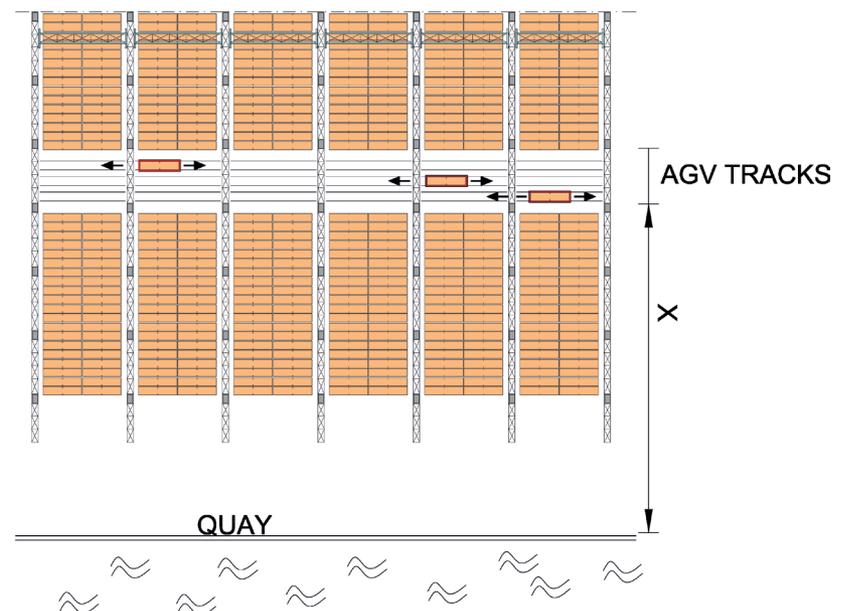

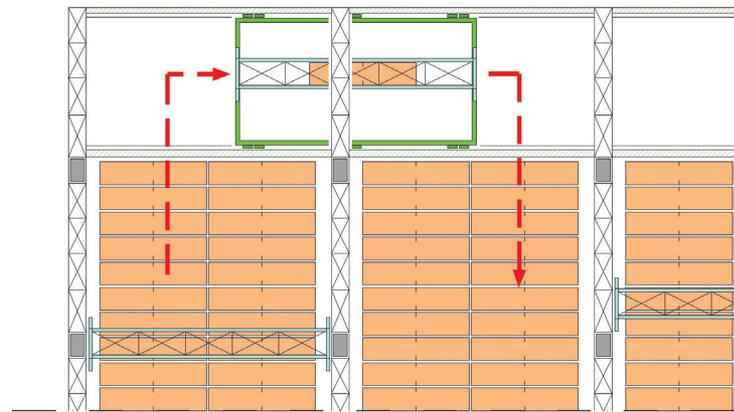

For a 'block' within the stack area that consists of 6 stack lanes (180m wide and 300m long) with two OHBC's per stack lane (12 in total), the investment will be at least 20% lower than a traditional configuration with 10 RMG's in an equal area. The savings on operational costs per TEU are much higher.

PLACEMENT

Positioning an OHBC in another stack lane can be done by a 'shunter' at the end of a stack lane. Due to the ability to vary the number of OHBC's over the length of one stack lane, we found that even on a terminal with a high transshipment rate there is no need to choose side-loaded systems parallel to the quay (unless other factors are more determined). In case of very high transshipment rates, an extra one directional AGV transport lane parallel to the quay across the perpendicular stack lanes will be sufficient (see Figure 5).

The distance between the quay and an extra lane, and the number of AGV tracks in this lane, will follow from the logistical calculations. All movements in this extra lane reduce the movements in the STS area. Also, the total transport distance of a container will be much less than in case of a side-loaded RMG system.

Another important advantage of the OHBC configuration is that truck

loading can be fully integrated within perpendicular stack lanes so the driving direction can be parallel to the quay without any backward driving at all. Therefore, coupled combinations of 3 x 20ft are also possible (see Figure 6).

CONCLUSION

Although in this article I have confined myself to stack operations, it may be clear that with a higher performance in stack operations, it will be possible to achieve a higher productivity of STS cranes as well. Simulations carried out by TBA Netherlands have shown the industry that the productivity of a current STS crane working with two-directional AGV's could increase productivity by almost 70%, while the number of AGV's per quay crane can be cut down by 50%. This very positive effect shows that the implementation of the NGICT stack configuration on existing terminals can lead to much higher performance. However, the utmost profit of the OHBC configuration will be achieved when the stack area is fully integrated into the ship-to-shore area, which is one of the main principles of the NGICT-concept.

ABOUT THE AUTHOR

Frans Koch, founder of the Koch Consultancy Group (1994), forms together with his son Mathé, the general management of the team of engineers and architects in the Netherlands who constitute Koch Consultancy Group. Both Frans and Mathé are both registered designers and hold a PMSE in structural engineering.

ABOUT THE ORGANISATION

Koch Consultancy Group consists of Raadgevend Ingenieursburo F. Koch B.V., Allant Architecten B.V. and Koch Projectmanagement, a local multidisciplinary organisation of consultants, architects and engineers. Its portfolio concentrates on projects in favour of industry, harbour and marine structures, civil works, buildings, energy production plants and wind turbines.

NGICT TODAY

Since the first article in February 2015, Edition 65, of the three part series 'A new concept in handling mega ships' we are quite happy with the reactions so far. Despite implementation of a new concept in container world would usually take more than ten years, we consider ourselves lucky because the circumstances play into our hands.

On one hand bigger ships, low shipping rates, bigger call sizes and longer berth times bring pressure on the terminal operators to improve their performance. On the other hand, low terminal productivity, the fact that current equipment has reached its limit, the impact on the environment, the huge geographical footprint, energy saving, and last but not least, the drive for safety, all exercise pressure on the innovative power of the terminal designers and manufacturers of the terminal equipment.

THE NECESSITY OF A GAME-CHANGER

Because mega vessels require 300 container berth moves per hour, further improving of current concepts is not the answer. Only the OHBC concept for stack operations will prove to be the solution for the present issues.

OHBC STACK OPERATIONS A MAJOR INNOVATION

Implementation of passing overhead cranes in the same stack lane is a simple way to increase the productivity with relatively low investment and low risks. These innovative OHBC stack operations are independent in respect to the existing transport equipment between the STS area and stack area, which makes a phased implementation possible.

Because the OHBC system is able to achieve much higher productivity than the current generation RMG and RTG stack cranes, it does not matter whether container transport will be executed by AGVs, lift AGVs, shuttle carriers, terminal tractors or even straddle carriers. Regardless, OHBCs are waiting for the delivery of the container.

An existing terminal does not have to change its STS cranes, nor its horizontal transport equipment, nor the distance between STS area and stack area. Old and new can easily work together during a conversion period.

MAXIMAL FLEXIBILITY

An added benefit in the OHBC system is the flexibility to shunt a third overhead crane into certain stack lanes during peak periods to deal with higher demands. In this case the productivity will be more than twice as high when compared to RMGs. And of course, the redundancy in case of disruptions or maintenance and the possibility of dual cycling in stack operations are unique.

CURRENT SITUATION

As stated in my original February 2015 paper, we are promoting the OHBC solution for stack operations and we are happy at the amount of interest we have received from all over the world. We are already involved in a number of feasibility studies with terminal operators, in which we deliver the logistics, as well the economic calculations and the general drawings. Every time the return on investment proves to be very short and very favorable compared to current systems.

THE FUTURE

If the feasibility studies we are currently working on turn into concrete orders, it could mean approximately 30 OHBCs for inland terminals and for empty depots, with up to 250 for deep sea terminals. And that's only the beginning. One crane manufacturer in the Netherlands is ready to start production as soon we get the green light for one of the inland project.

When deep sea terminals are going to plan implementation of the OHBC system in their new build expansions or as replacement of the existing equipment, we have to scale up to mass production in cooperation with one or two bigger suppliers which are active worldwide.

The new OHBC system enables terminal operators who have not yet switched to the current automated stacking cranes to skip that generation completely. For terminal operators who have already made the switch to the current modern ASCs, it will make sense to consider the OHBC system for future expansion.
